

Powershell - Setup & Introduction

Once or twice, *you may have used the cmd on WINDOWS*

This *used to be* the **tool** (*could be* considered a coding language) for technical users to manage Window's systems, but as technology aged; the older structure it was based off of was **no longer working**.

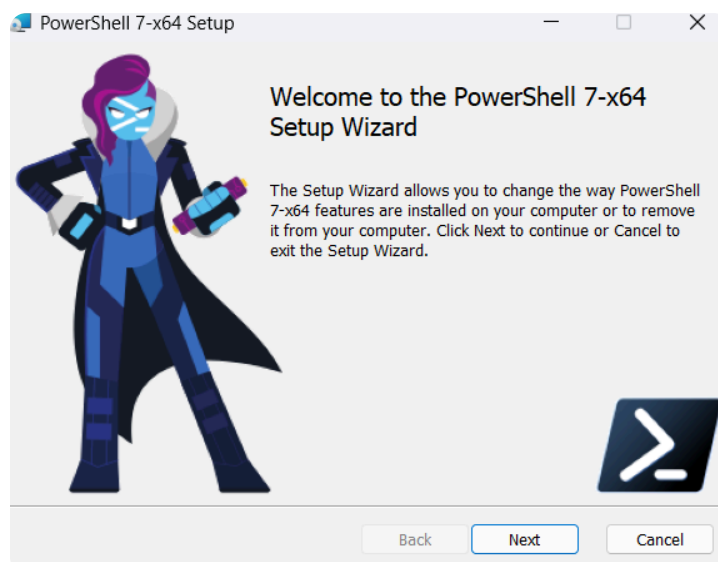

- POWERSHELL, was **Microsoft's fix**. It's based on newer paradigms, to make easier system management.
- Powershell is used primarily for Help Desk Jobs or "Windows Servers"

Furthermore, **Version 7** of Powershell aims for **CROSS OS management**, but we have to install that separately.

Let's set it up:

- Follow this link, and use the first download link
- [🌐 Install PowerShell on Windows - PowerShell](#)

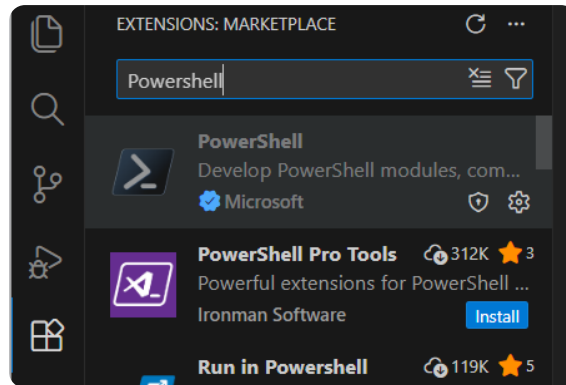

Follow the **installation wizard** (just click Next & OK)

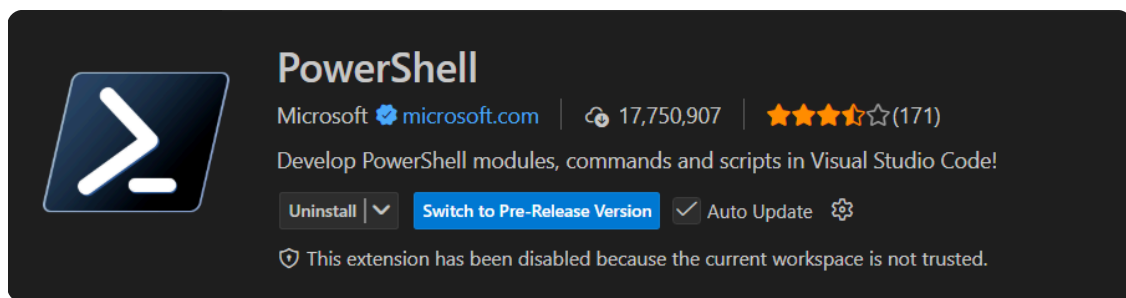

Now, we need to open **VSCode**; because we CAN'T actually write our code inside *Powershell* 7. (Install it if you haven't)

Go to **Extensions**,

- Search up *Powershell*

- Enable it

It'll *automatically* make an **Untitled File** called **Untitled-1.ps1**

- Now, we MAY want to be able to run our **custom scripts** WITHOUT going into the folder they're stored in.
 - This is somewhat *optional*, it'll just be that you have to actually go to the folder you saved something in to run it.

Let's do that:

Create a folder you wish to store your scripts in

- Here's mine (We'll make all of our files in here)

```
> Documents > ps-scripts
```

After that

- Inside Documents create a Folder Called Powershell

```
> Documents > Powershell
```

Open the *folder above* into VSCode

- Create a *file* called **Microsoft.PowerShell_profile.ps1**
- Paste **this command**

```
> Microsoft.PowerShell_profile.ps1 > ...  
1  $env:Path += ";$env:USERPROFILE\Documents\ps-scripts"  
2
```

```
$env:Path += ";$env:USERPROFILE\Documents\ps-scripts"
```

Now, we can make our files **INSIDE** Documents/ps-scripts and it'll run anywhere. Next PDF shows the basics of Powershell.
